SONET/SDH Circuit Emulation Service Over Packet (CEP) Management
Information Base Using SMIv2
draft-ietf-pwe3-cep-mib-07.txt

Status of this Memo

By submitting this Internet-Draft, each author represents that any applicable patent or other IPR claims of which he or she is aware have been or will be disclosed, and any of which he or she becomes aware will be disclosed, in accordance with Section 6 of BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at http://www.ietf.org/ietf/1id-abstracts.txt
The list of Internet-Draft Shadow Directories can be accessed at http://www.ietf.org/shadow.html.

Abstract

This memo defines an experimental portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it describes managed objects for modeling Native Service Processing of SONET/SDH circuits over a Packet Switch Network (PSN).
1 Introduction

This document describes a model for managing encapsulated SONET Time Division Multiplexed (TDM) digital signals for transmission over a Packet Switched Network (PSN).

This document is closely related to [CEP], which describes the technology to encapsulate TDM signals and provide the Circuit Emulation Service over a Packet Switched Network (PSN).

The model for CEP management is a MIB module. The CEP MIB module described in this document works closely with the MIB modules described in [PWMIB] and the textual conventions defined in [PWTC].

In the spirit of the [RFC2863], a CEP connection will be a pseudo-wire (PW), and will therefore not be represented in the ifTable.

CEP is currently specified to carry "structured" SONET paths, meaning that each SONET PATH/VT within the section/line/path can be processed separately. The SONET section/line/path interface stack is modeled within [RFC3592].

Comments should be made directly to PWE3 group at pwe3@ietf.org.

This memo does not, in its draft form, specify a standard for the Internet community.

Conventions used in this document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC-2119 [BCP14].
CEP terminology comes from the CEP draft that describes a mechanism for transporting SONET Time Division Multiplexed (TDM) digital signals over a packet-oriented network. The mechanism for structured (as outlined in the CEP draft) terminates the SONET section and line overhead and then breaks the SONET path’s Synchronous Payload Envelope (SPE) into fragments for transmission over a PSN. Mechanism for terminating of the SONET path overhead and extracting SONET VTs are also described in [CEP]. Mechanisms for Fractional SONET SPE emulation are described in [CEP]. A CEP header is appended at the beginning of each fragment to provide information regarding where the SPE begins within the packet stream, a sequence number, and pointer adjustment information (see [CEP]).

"Outbound" references the traffic direction where a SONET path’s payload (SPE) is received, adapted to packet, assigned a PW label, and sent into the PSN.

Conversely, "inbound" is the direction where packets are received from the PSN, packet payloads are reassembled back into an SPE, and inserted as a SONET path into the SONET section and line.

Since a SONET path is bi-directional and symmetrical, CEP uses the same SONET time-slot, SONET width and packet size. Inbound and outbound PW labels may differ.

3 The Internet-Standard Management Framework

For a detailed overview of the documents that describe the current Internet-Standard Management Framework, please refer to section 7 of RFC 3410 [RFC3410].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This memo specifies a MIB module that is compliant to the SMIv2, which is described in STD 58, RFC 2578 [RFC2578], STD 58, RFC 2579 [RFC2579] and STD 58, RFC 2580 [RFC2580].

4 CEP MIB module architecture

The CEP MIB module is part of the PW MIB modules architecture, as described in [PWMIB], and serves as one of the PW type-specific MIB module

For clarity of the description below, in most cases we refer to the PATH SONET signal configuration only. When configuring VT mode as described in [CEP], the same apply for the VT level.
1.1 Summary of CEP MIB

- The CEP PW Table (pwCepTable) contains the SONET Path/VT ifIndex, SONET Path Time slot, the pwCepCfgTable index, config error indications, and various status indications.

- The CEP PW Configuration Parameter Table (pwCepCfgTable) has objects for CEP PW configuration. In situations where sets of config objects are common amongst more than 1 CEP PW, a single entry here may be referenced by many pwCepTable entries.

- The CEP Performance Current Table (pwCemPerfCurrentTable) contains CEP stats for the current 15-minute period.

- The CEP Performance 15 Minutes Interval Table (pwCemPerfIntervalTable) is similar to the pwCemPerfCurrentTable. It contains historical intervals (usually 96 15-minute entries to cover a 24 hour period).

Note: the performance interval statistics are supported by CEP due to the very function of CEP - that is, processing SONET. See [RFC3592].

- The CEP Performance 1 day Table (pwCepPerf1DayTable) contains statistics accumulated during the current day and contains previous days historical statistics.

- The CEP Fractional Table (pwCepFracTable) adds configuration and monitoring parameters for fractional SPE PWs.

- The Conformance Config Table (pwCepConformanceCfgTable) allows the vendor to specify the extent to which certain objects are supported (or not).

1.2 CEP configuration Step by Step

Configuring a CEP PW involves the following steps.

First create an entry in the pwTable and configure the PSN tunnels:

- Follow steps as defined in [PWMIB].

Configure the SONET Path parameters:

- Set the SONET path width in the sonetPathCurrentTable [RFC3592].

- Set the SONET path index and the SONET path starting time slot in the pwCepTable.

NOTE: The agent will have created an entry in the pwCepTable based on the entry created in the pwTable.

Configure the CEP PW:

- If necessary, create an entry in the pwCepCfgTable (a suitable entry may already exist). Set packet length, etc.
- Set the index of this pwCepCfgTable entry in the pwCepTable.

Observe the CEP PW:

- Once a CEP PW is operational, the pwCepPerfCurrentTable, pwCepPerfIntervalTable, and pwCepPerf1DayTable are used to monitor the various counts, indicators, and conditions of the PW.

Conforming to the CEP MIB objects:

- The pwCepConformanceCfgTable is used to state True/False whether certain objects are supported. An ASCII string object is available with every True/False object as a means to explain the extent of ‘true’ support, or perhaps explain why the ‘false’ was set.

5 Example of CEP PW Setup

In this section we provide an example of using the MIB objects described in section 8 to set up a CEP PW (width of 3 STSs, starting at time slot 1). While this example is not meant to illustrate every permutation of the MIB, it is intended as an aid to understanding some of the key concepts. It is meant to be read after going through the MIB itself. See [PWMIB] for an example of setting up PSN Tunnels.

First configure the SONET path width, starting time-slot, and associated CEP PW. In this case, an STS-3c starts at SONET time slot 1 (and is distributed normally within the SONET frame). In the following example, the ifIndex for the sonetPathCurrentEntry is 23, while the pwCepCfgTable index is 9.

```
In [RFC3592] sonetPathCurrentEntry (ifIndex = 23) :
{
    sonetPathCurrentWidth           = 3,
    sonetPathCurrentStatus
    ...
    ...
}
```

Create an entry in the pwCepCfgTable (index = 9) :

```
{  
    pwCepCfgSonetPayloadLength    = 783  -- payload bytes
    pwCepCfgMinPktLength          = 0     -- no minimum
    pwCepCfgPktReorder            = true
    pwCepCfgEnableDBA             = unequipped
    pwCepCfgRtpHdrSuppress        = false
    pwCepCfgJtrBfrDepth           = 500    -- micro-seconds
    pwCepCfgConsecPktsInsync      = 2      -- Exit LOPS state
    pwCepCfgConsecMissingOutSync  = 10     -- Enter LOPS state
    pwCepCfgPktErrorPlayOutValue  = 0xFF   -- All ones
    pwCepCfgMissingPktsToSes      = 3      -- packets,
}
Check that there is no error bit set in pwCepConfigError.

In the PW MIB module: Get a new index and create a new pwTable entry using pwIndexNext (here, the PW index = 83) and pwRowStatus. In this new entry, set pwType to 'cep'. This should create a new entry in the pwCepTable. Set up and the SONET path ifIndex, SONET path time slot, and Cfg Table indexes within this new pwCep table entry:

```c
{
    pwCepSonetIfIndex = 23 -- Index of associated entry
                        -- in sonetPathCurrent table.

    pwCepCfgIndex = 9  -- Index of associated entry
                       -- in pwCepCfg table (above).
}
```

Verify that none of the error bits are set in pwCepSonetConfigError.

pwCepSonetIfIndex OBJECT-TYPE
SYNTAX        InterfaceIndexOrZero
MAX-ACCESS    read-write
STATUS        current
DESCRIPTION
"This is a unique index within the ifTable. It represents
the interface index for the SONET path for SPE emulation
(RFC3593 section 3.3), an interface index for the SONET
VT (RFC3593 section 3.4) if the VT to be emulated is
extracted a SONET signal or locally mapped from a physical
interface.

A value of zero indicates an interface index that has yet
to be determined.
Once set, if the SONET ifIndex is (for some reason) later
removed, the agent MAY delete the associated PW rows
(e.g., this pwCepTableEntry). If the agent does not
delete the rows, it is recommended that the agent set this
object to zero."

pwCepIndications OBJECT-TYPE
SYNTAX          BITS {
   missingPkt  ( 0),
   ooRngDropped( 1),
   jtrBfrUnder ( 2),
   pktMalformed( 3),
   lops        ( 4),
   cepRdi      ( 5),
   cepAis      ( 6),
   badHdrStack ( 7),
   cepNeFailure( 8),
   cepFeFailure( 9)
}

Definitions:

‘missingPkt’ (0) - While playing out a sequence of packets, a
 packet(s) was determined to be missing based on a gap in the
 CEP sequence number. Note: If the implementation supports
 packet re-ordering, detecting gaps should not take place as
 packets arrive, only as they are played out - this gives
 time for mis-ordered packets to arrive late.

‘ooRngDropped’ (1) - Packet(s) arrives that is outside the
 range of the jitter buffer. This may be because the
 jitter buffer is full, or the sequence number addresses
 a buffer outside the current jitter buffer range, or
 addresses an already occupied buffer within range.
 Whether or not packet re-ordering is supported by the
 implementation, this indication MUST be supported.

‘jtrBfrUnder’ (2) - The jitter buffer underflowed due to
 not enough packets arriving as packets were being
 played out.

‘pktMalformed’ (3) - Any error related to unexpected
 packet format (except bad header stack) or unexpected
 length.
'lops'(4) - Loss Of Packet Synchronization.

'cepRdi'(5) - Circuit Emulation over Packet Remote Defect Indication. Generated by the remote CEP de-packetizer when detecting LOPS. Note: not generated by the remote SONET function. See draft-ietf-pwe3-sonet.

'cepAis'(6) - Remote CEP packetizer has detected AIS on its incoming SONET stream. Note: cepAis MUST NOT (in itself) cause a CEP down notification.

'badHdrStack'(7) - This indication is set when the number of CEP header extensions detected in incoming packets does not match the expected number.

'cepNeFailure'(8) - Set when CEP-NE failure is currently declared.

'cepFeFailure'(8) - Set when CEP-FE failure is currently declared.

This object MUST hold the accumulated indications, until the next SNMP write that clear the indication(s).

Writing a non zero value MUST fail.

Currently there is no hierarchy of CEP defects.

The algorithm used to capture these indications is implementation specific."

### pwCepCfgIndexNext

**OBJECT-TYPE**

**SYNTAX**      PwCepCfgIndex  
**MAX-ACCESS**  read-only  
**STATUS**      current  
**DESCRIPTION**

This object contains an appropriate value to be used for pwCepCfgIndex when creating entries in the pwCepCfgTable. The value 0 indicates that no unassigned entries are available. To obtain the value of pwCepCfgIndex for a new entry in the pwCepCfgTable, the manager issues a management protocol retrieval operation to obtain the current value of pwCepCfgIndex. After each retrieval operation, the agent should modify the value to reflect the next unassigned index. After a manager retrieves a value the agent will determine through its local policy when this index value will be made available for reuse.

cannot be supported by the local agent."
::= { pwCepCfgEntry 2 }

pwCepSonetPayloadLength OBJECT-TYPE
SYNTAX Unsigned32
MAX-ACCESS read-create
STATUS current
DESCRIPTION "The number of SONET bytes of the Path or VT carried as
payload within one packet. For example, for STS-1/VC-3 SPE
circuits, value of 783 bytes indicates that each packet
carries payload equivalent to one frame. For VT1.5/VC11
circuits, a payload length of 104 bytes indicates that each
packet carries payload equivalent to one VT1.5 super-frame."
The actual payload size may be different, due to bandwidth reduction modes, e.g. DBA mode or dynamically assigned fractional SPE. This length applies to inbound and outbound packets carrying user payload. Although there is no control over inbound packets, those of illegal length are discarded and accounted for (see pwCepPerf...Malformed.) The default values are determined by the pwCepType: 783 for pwCepType equal spe(2) or fracSpe(3). For vt(3) modes, the applicable super-frame payload size is the default value.

SYNTAX       Unsigned32
UNITS        "micro-seconds"
MAX-ACCESS   read-create
STATUS       current
DESCRIPTION   "This setting configures the number of microseconds
of expected packet delay variation for this CEP PW
over the PSN.

The actual jitter buffer MUST be at least twice this value for proper operation, and is implementation specific.

If configured to a value not supported by the implementation, the agent MUST return an error code 'jtrBfrDepth' in 'pwCepConfigError'.

```::= { pwCepCfgEntry 8 }
--
-- The following counters work together to integrate (filter)
-- errors and the lack of errors on the CEP PW. An error is
-- caused by a missing packet. Missing packet can be a result
-- of: packet loss in the network, (uncorrectable) packet out
-- of sequence, packet length error, jitter buffer overflow,
-- and jitter buffer underflow. The result is declaring whether
-- or not the CEP PW is in Loss of Packet Sync (LOPS) state.

Zelig et al Expires August 2006 28
CEP bridges the SONET and packet worlds. In the packet world, counts typically start from the time of service creation - and don’t stop. In the SONET world, counts are kept in 15 minute intervals. The PW CEP MIB supports both methods. The current 15 minute interval counts are in this table. The interval and total stats are in tables following this.

This table provides per CEP PW performance information. HC (high capacity) counters are required for some counts due to the high speeds expected with CEP services. A SONET path of width 48 (STS-48c) can rollover non-HC counters in a few minutes.

An entry in this table is created by the agent for every pwCep entry. After 15 minutes, the contents of this table entry are copied to a new entry in the pwCepPerfInterval table and the counts in this entry are reset to zero.

pwCepPerfIntervalNumber OBJECT-TYPE
SYNTAX      Integer32 (1..96)
MAX-ACCESS  not-accessible
STATUS      current
DESCRIPTION
"A number (normally between 1 and 96 to cover a 24 hour
period) which identifies the interval for which the set
of statistics is available. The interval identified by 1
is the most recently completed 15 minute interval, and
the interval identified by N is the interval immediately
preceding the one identified by N-1. The minimum range of
N is 1 through 4. The default range is 1 through 32. The
maximum value of N is 1 through 96."

7 Security considerations

It is clear that this MIB module is potentially useful for monitoring of CEP PWs. This MIB can also be used for configuration of certain objects, and anything that can be configured can be incorrectly configured, with potentially disastrous results.

There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a non-secure environment without proper protection can have a negative effect on network operations. These are the tables and objects and their sensitivity/vulnerability:

- the pwCepTable, pwCepCfgTable and pwCepFracTable contains objects to CEP PW parameters on a Provider Edge (PE) device. Unauthorized access to objects in these tables could result in disruption of traffic on the network. The use of stronger mechanisms such as SNMPv3 security should be considered where possible. Specifically, SNMPv3 VACM and USM MUST be used with any v3 agent which implements this MIB module. Administrators should consider whether read access to these objects should be allowed, since read access may be undesirable under certain circumstances.

Some of the readable objects in this MIB module "i.e., objects with a MAX-ACCESS other than not-accessible" may be considered sensitive or vulnerable in some network environments. It is thus important to control even GET and/or NOTIFY access to these objects and possibly to even encrypt the values of these objects when sending them over the network via SNMP. These are the tables and objects and their sensitivity/vulnerability:
the pwCepTable, pwCepPerfCurrentTable, pwCepPerfIntervalTable and pwCepPerf1DayTable collectively show the CEP pseudo wire connectivity topology and its performance characteristics. If an Administrator does not want to reveal this information, then these tables should be considered sensitive/vulnerable.

SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure "for example by using IPSec", even then, there is no control as to who on the secure network is allowed to access and GET/SET "read/change/create/delete" the objects in this MIB module.

It is RECOMMENDED that implementers consider the security features as provided by the SNMPv3 framework "see [RFC3410], section 8", including full support for the SNMPv3 cryptographic mechanisms "for authentication and privacy".

Further, deployment of SNMP versions prior to SNMPv3 is NOT RECOMMENDED. Instead, it is RECOMMENDED to deploy SNMPv3 and to enable cryptographic security. It is then a customer/operator responsibility to ensure that the SNMP entity giving access to an instance of this MIB module, is properly configured to give access to the objects only to those principals "users" that have legitimate rights to indeed GET or SET "change/create/delete" them.

12 Intellectual Property Rights

The IETF takes no position regarding the validity or scope of any Intellectual Property Rights or other rights that might be claimed to pertain to the implementation or use of the technology described in
this document or the extent to which any license under such rights might or might not be available; nor does it represent that it has made any independent effort to identify any such rights. Information on the procedures with respect to rights in RFC documents can be found in BCP 78 and BCP 79.

Copies of IPR disclosures made to the IETF Secretariat and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementers or users of this specification can be obtained from the IETF on-line IPR repository at http://www.ietf.org/ipr.

The IETF invites any interested party to bring to its attention any copyrights, patents or patent applications, or other proprietary rights that may cover technology that may be required to implement this standard. Please address the information to the IETF at ietf-ipr@ietf.org.

13 IANA considerations

The MIB module in this document uses the following IANA-assigned OBJECT IDENTIFIER values recorded in the SMI Numbers registry:

<table>
<thead>
<tr>
<th>Descriptor</th>
<th>OBJECT IDENTIFIER value</th>
</tr>
</thead>
<tbody>
<tr>
<td>pwCepStdMIB</td>
<td>{ transmission XXXX }</td>
</tr>
</tbody>
</table>

Editor’s Note (to be removed prior to publication): the IANA is requested to assign a value for "XXXX" under the 'transmission' subtree and to record the assignment in the SMI Numbers registry. When the assignment has been made, the RFC Editor is asked to replace "XXXX" (here and in the MIB module) with the assigned value and to remove this note.
